Complaint classification

Submitted by Ujjwal Mishra [9834486042] [Email: ujjwalmishra49@gmail.com]

• Problem Statement: Development of an NLP Model for Text Analytics and

Classification

• Objective:

To develop an NLP model that categorizes complaint based on victim, type of fraud and other relevant parameters used for text classification and preparing the final model.

• Outputs:

Text Pre-processing: Tokenization, stop word removal, stemming, and text cleaning to prepare data.

Model Development: Selection of a suitable NLP model for text classification

Accuracy Measurement: Evaluate the model based on metrics such as accuracy, precision, recall, and F1-score.

Step 1: Import Necessary Libraries

We import several libraries essential for preprocessing, model building, evaluation, and visualization:

- pandas & numpy: Used for data manipulation and numerical operations.
- re: Used for regular expressions to clean text.
- matplotlib & seaborn: For visualizing data and results.
- **sklearn modules**: For splitting datasets, feature extraction, model training, and evaluation.
- **nltk**: For natural language processing (NLP), including tokenization, stemming, and stopword removal.

The following specific tools were utilized:

- **TfidfVectorizer**: Converts text data into a numerical form by calculating Term Frequency-Inverse Document Frequency (TF-IDF) scores.
- MultinomialNB: A Naive Bayes classifier optimized for text data.
- **Evaluation Metrics**: accuracy_score, precision_score, recall_score, fl_score, and a confusion matrix.

Step 2: Load and Inspect Data

We load training and testing datasets using pandas.read_csv:

- train_data: Contains labeled data for training the model.
- test data: Contains unlabeled data for evaluation.

Sample data is displayed for inspection using .head() to ensure proper loading.

Step 4: Analyze and Visualize Dataset

Goal: Understand category distribution in the training dataset.

- 1. A bar plot displays the count of complaints for each category using Seaborn.
- 2. The plot highlights any class imbalance, which is crucial for evaluating model performance and fairness.

Step 5: Convert Text to Numerical Form

TF-IDF Vectorization:

- Converts text into a numerical matrix where each feature represents a word (or term).
- TF-IDF score captures the importance of a term in a document relative to the entire corpus.
- max_features=5000 ensures that only the 5,000 most relevant terms are considered to reduce dimensionality.

Step 6: Train-Test Split

We divide the data into training and validation sets:

- **80% Training Data**: For model training.
- 20% Validation Data: For evaluation.

Random splitting is used to ensure a fair division of samples.

Step 7: Model Development

The **Multinomial Naive Bayes** (**MultinomialNB**) classifier is chosen due to its suitability for text classification:

- Assumes features (words) are conditionally independent given the class.
- Efficient and effective for high-dimensional, sparse data like TF-IDF matrices.

The model is trained using model.fit on the training data.

Step 8: Evaluate the Model

- 1. **Predictions**: The model generates predictions on validation data.
- 2. Evaluation Metrics:
 - Accuracy: Proportion of correctly classified samples.
 - Precision: Focuses on false positives, measuring correctness of positive predictions.

- o **Recall**: Measures the ability to capture true positives.
- o **F1-Score**: Harmonic mean of precision and recall, balancing both.
- o Classification Report: Provides per-class precision, recall, and F1-scores.

3. Confusion Matrix:

- o Visualizes true vs. predicted labels.
- o Helps identify patterns of misclassification.

The confusion matrix is displayed using a heatmap for easy interpretation.

Step 10: Predict New Input

The predict_new_text function allows prediction on arbitrary input text. Steps include:

- 1. Preprocessing the input text.
- 2. Transforming it using the trained TF-IDF vectorizer.
- 3. Generating predictions and confidence scores.

Evaluation Metrics Overview

- 1. **Accuracy**: Measures overall correctness; however, it can be misleading in imbalanced datasets.
- 2. **Precision**: High precision means fewer false positives.
- 3. **Recall**: High recall means fewer false negatives.
- 4. **F1-Score**: Balances precision and recall, ideal for imbalanced classes.

Summary of the Process

- 1. **Data Preparation**: Preprocessing text to clean and tokenize it.
- 2. **Feature Engineering**: Converting text into numerical form via TF-IDF.
- 3. **Model Training**: Using a Multinomial Naive Bayes classifier.
- 4. **Evaluation**: Assessing performance using robust metrics and visualizations.
- 5. **Prediction**: Classifying test data and new inputs with confidence scores.

The notebook was run on Google Colab Notebook and following findings were noted:

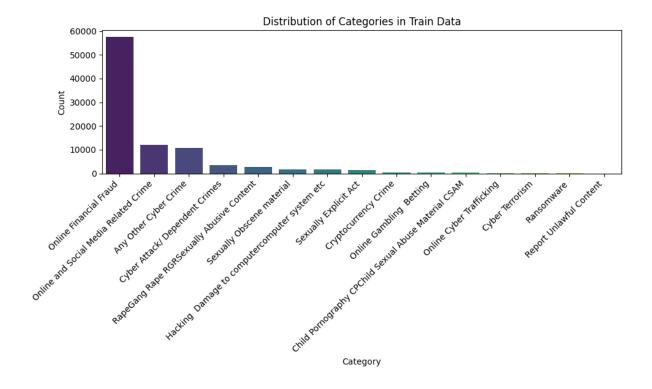

Model Evaluation Metrics:

Accuracy: 0.74

Precision: 0.72

Recall: 0.74

F1-Score: 0.72
